# Fine splitting in the charmonium spectrum with a channel coupling effect ${ }^{*}$ 

YANG Chun（杨春）${ }^{1}$ LI Bao－Fei（李瀑飞）${ }^{1}$ CHEN Xiao－Lin（陈晓林）$)^{2}$ DENG Wei－Zhen（邓卫真）${ }^{1 ; 1)}$<br>${ }^{1}$ Department of Physics and State Key Laboratory of Nuclear Physics and Technology， Peking University，Beijing 100871，China<br>${ }^{2}$ Department of Physics，Peking University，Beijing 100871，China

#### Abstract

We study the fine splitting in the charmomium spectrum in the quark model with the channel coupling effect，including $\mathrm{DD}, \mathrm{DD}^{*}, \mathrm{D}^{*} \mathrm{D}^{*}$ and $\mathrm{D}_{\mathrm{s}} \mathrm{D}_{\mathrm{s}}, \mathrm{D}_{\mathrm{s}} \mathrm{D}_{\mathrm{s}}^{*}, \mathrm{D}_{\mathrm{s}}^{*} \mathrm{D}_{\mathrm{s}}^{*}$ channels．The interaction for channel coupling is constructed from the current－current Lagrangian related to the color confinement and the one－ gluon exchange potentials．By adopting the massive gluon propagator from the lattice calculation in the nonperturbative region，the coupling interaction is further simplified to four－fermion interaction．The numerical calculation still prefers the assignment $1^{++}$of $\mathrm{X}(3872)$ ．

## 1 Introduction

A series of hidden charm states，the so－called X ， Y，Z，have been discovered and confirmed by exper－ iments since 2003．The nature of these narrow res－ onances has attracted much attention，because their properties are not consistent with the prediction of the quark model．

The typical $\mathrm{X}(3872)$ state，which was discovered in 2003 by the Belle Collaboration［1］and subse－ quently confirmed by the CDF Collaboration［2］and BABAR Collaboration［3］，etc．，is now listed with $M_{\mathrm{X}}=3872.2 \pm 0.8 \mathrm{MeV}, \Gamma_{\mathrm{x}}=3.0_{-1.4}^{+1.9} \pm 0.9 \mathrm{MeV}$ in PDG［4］．Its quantum numbers were inferred $J^{P C}=1^{++}$or $2^{-+}$．The corresponding charmonium candidate in the quark model is $2^{3} P_{1}$ or $1^{1} D_{2}$ respec－ tively．

The mass of the $2^{3} P_{1}$ state in the quark model is $\sim 100 \mathrm{MeV}$ above $M_{\mathrm{X}}$ ．However，the channel cou－ pling effects by the creation of open charmed meson pairs can produce significant mass shift to the bare charmonium spectrum．In Ref．［5］，only the fine split－ ting in the mass shift induced by open－charm states is considered．In Refs．［6，7］，the whole mass shift is considered to lower the bare mass of the excited
charmonium state．The mass shift can also be hand－ ily treated by introducing screened potential into the quark model［8］．

The proximity of the $\mathrm{X}(3872)$ to $\mathrm{DD}^{*}$ threshold implies that the cusp scenario may be important［9］． The cusp can be calculated from channel coupling and the result is in qualitative agreement with ex－ periment［10］．The observed but Okubo－Zweig－Iizuka （OZI）forbidden decay channel $\rho J / \psi$ is also consid－ ered in Ref．［11］．

Recently，a study of the $\pi^{+} \pi^{-} \pi^{0}$ mass distribu－ tion from the $\mathrm{X}(3872)$ decay by the BABAR Collab－ oration favors the negative parquantum numbersity assignment $2^{-+}[12]$ ．However，the mass of the corre－ sponding charmonium state $1^{1} D_{2}$ in the quark model is $\sim 100 \mathrm{MeV}$ below $M_{\mathrm{X}}$ ．Since the $\psi(3770)$ is as－ signed to $1^{3} D_{1}$ in the quark model，the assignment $2^{-+}$seems to conflict with the small fine splitting in c $\overline{\mathrm{c}}$ $1 D$ multiplet from the quark model calculation［13］．

The mechanism of channel coupling is the same as strong decay＇s．The simplest decay model is the so－called ${ }^{3} P_{0}$ model based on the flux－tube－breaking model［14，15］．Another model is the Cornel model which tries to relate the pair－creation interaction to the potential in the quark model $[16,17]$ ．The Cornel

[^0]model assumes the Lorentz vector confinement so the total vector potential is
\[

$$
\begin{equation*}
V(r)=-\frac{\kappa}{r}+\frac{r}{a^{2}} \tag{1}
\end{equation*}
$$

\]

Thus in the Cornel model the decay amplitude from the one-gluon exchange and that from the confinement add destructively. A similar calculation but using the Lorentz scalar confinement shows that the decay amplitude from the scalar linear confinement is too large [18].

The lattice calculation shows that the gluon propagator is quite different in the nonperturbative region. The gluon may get a mass of about $600-1000 \mathrm{MeV}$ [19-21]. A non-vanishing gluon mass is used in the phenomelogical calculation of the diffractive scattering [22] and radiative decays of the $\mathrm{J} / \psi$ and $\Upsilon$ [23].

In this work, we will consider the fine splitting induced by channel coupling with open-charm states, including $\mathrm{DD}, \mathrm{DD}^{*}, \mathrm{D}^{*} \mathrm{D}^{*}$ and $\mathrm{D}_{\mathrm{s}} \mathrm{D}_{\mathrm{s}}, \mathrm{D}_{\mathrm{s}} \mathrm{D}_{\mathrm{s}}^{*}, \mathrm{D}_{\mathrm{s}}^{*} \mathrm{D}_{\mathrm{s}}^{*}$. Follwing the Cornel model, we will construct the model pair-creation interaction from the potential in the quark model, i.e. the scalar confinement plus the vector one-gluon exchange. With the assumption of the massive gluon propagator in the pair-creation process, we will obtain a simple effective four-fermion interaction which is quite similar to the case of weak interaction. In Sec. 2, we will introduce the channel coupling model. In Sec. 3, the numerical analysis is performed. Finally, we will give a brief summary.

## 2 The channel coupling model

In the simplest version of the channel coupling model [7], the hadronic state is assumed to be represented by

$$
\begin{equation*}
\left|\Psi_{\alpha}\right\rangle=\binom{c_{\alpha}\left|\psi_{\alpha}\right\rangle}{\sum_{i} \chi_{\alpha i}\left|M_{1}(i) M_{2}(i)\right\rangle} \tag{2}
\end{equation*}
$$

where the bare state $\left|\psi_{\alpha}\right\rangle$ is coupled to several mesonmeson channels $\left|M_{1}(i) M_{2}(i)\right\rangle$. The system Hamiltonian reads

$$
\hat{H}=\left(\begin{array}{cc}
\hat{H}_{\mathrm{c}} & \hat{V}  \tag{3}\\
\hat{V} & \hat{H}_{M_{1} M_{2}}
\end{array}\right)
$$

where $\hat{H}_{\text {c }}$ is the meson Hamiltonian of the quark model, with

$$
\begin{equation*}
\hat{H}_{\mathrm{c}}\left|\psi_{\alpha}\right\rangle=M_{\alpha}\left|\psi_{\alpha}\right\rangle \tag{4}
\end{equation*}
$$

In this work, $\hat{H}_{M_{1} M_{2}}$ includes only the free meson Hamiltonian, so

$$
\begin{equation*}
\hat{H}_{M_{1} M_{2}}=\hat{H}_{M_{1}}+\hat{H}_{M_{2}} \tag{5}
\end{equation*}
$$

The Hamiltonian in the non-relativistic quark potential model can always be written as [7]

$$
\begin{equation*}
\hat{H}_{\mathrm{c}}=\hat{H}_{0}+\hat{H}_{\mathrm{sd}} \tag{6}
\end{equation*}
$$

where $\hat{H}_{0}$ and $\hat{H}_{\text {sd }}$ are the spin-independent and spindependent parts respectively. The spin-independent part reads

$$
\begin{equation*}
\hat{H}_{0}=\frac{p^{2}}{2 \mu}+V(r)+C \tag{7}
\end{equation*}
$$

$\mu$ is the reduced mass. The potential $V(r)$ is usually taken to be a sum of the linear confinement plus the one-gluon exchange Coulomb potential:

$$
\begin{equation*}
V(r)=\sigma r-\frac{4}{3} \frac{\alpha_{\mathrm{s}}}{r} \tag{8}
\end{equation*}
$$

$\hat{H}_{\text {sd }}$ includes spin-spin, spin-orbit and tensor force:

$$
\begin{equation*}
H_{\mathrm{sd}}=V_{\mathrm{HF}}(r) \boldsymbol{S}_{1} \cdot \boldsymbol{S}_{2}+V_{\mathrm{LS}}(r) \boldsymbol{L} \cdot \boldsymbol{S}+V_{\mathrm{T}}(r) T \tag{9}
\end{equation*}
$$

which determines the fine splitting in the spectrum.
The off-diagonal interaction $\hat{V}$ is responsible for channel coupling. It depends on the pair-creation mechanism of the specific hadron decay model. The ${ }^{3} P_{0}$ model [14, 15] and the Cornel model [16, 17] are two popular decay models.

To describe the creation of a light-quark pair in the quark model, a plausible approach is to consider the quantum field expression of the quark potential $V(r)$. In the Cornell model, the quark potential is replaced by an instantaneous interaction [16, 17]

$$
\begin{equation*}
H_{\mathrm{I}}=\frac{1}{2} \int \mathrm{~d}^{3} x \mathrm{~d}^{3} y: \rho_{\mathrm{a}}(\boldsymbol{x}) \frac{3}{4} V(\boldsymbol{x}-\boldsymbol{y}) \rho_{\mathrm{a}}(\boldsymbol{y}): \tag{10}
\end{equation*}
$$

where

$$
\begin{equation*}
\rho_{\mathrm{a}}(\boldsymbol{x})=\sum_{\text {flavors }} \psi^{\dagger}(\boldsymbol{x}) \frac{1}{2} \lambda_{\mathrm{a}} \psi(\boldsymbol{x}) \tag{11}
\end{equation*}
$$

is the quark color-charge-density operator and $\psi(\boldsymbol{x})$ is the quark field operator. As the spin splitting in charmonium spectrum and the lattice gauge calculation indicate that the confinement current should be the Lorentz scalar, in Ref. [18] the instantaneous interaction is replaced by the scalar confinement interaction plus the vector one-gluon exchange.

Following the Cornel model, here we will model the pair-creation from the quark model. We first assume the nonlocal current-current action of the quark interaction [24]:

$$
\begin{align*}
A= & -\frac{1}{2} \int \mathrm{~d}^{4} x \mathrm{~d}^{4} y \bar{\psi}(x) \gamma_{\mu} \frac{1}{2} \lambda_{\mathrm{a}} \psi(x) G(x-y) \bar{\psi}(y) \gamma^{\mu} \\
& \times \frac{1}{2} \lambda_{\mathrm{a}} \psi(y)-\frac{1}{2} \int \mathrm{~d}^{4} x \mathrm{~d}^{4} y \bar{\psi}(x) \\
& \times \frac{1}{2} \lambda_{\mathrm{a}} \psi(x) S(x-y) \bar{\psi}(y) \frac{1}{2} \lambda_{\mathrm{a}} \psi(y) \tag{12}
\end{align*}
$$

The vector kernel $G$ is obtained from the onegluon propagator. In the momentum space

$$
\begin{equation*}
G\left(q^{2}\right)=-\frac{4 \pi \alpha_{\mathrm{s}}}{q^{2}} \tag{13}
\end{equation*}
$$

The scalar kernel $S(x-y)$ is obtained from the linear confinement

$$
\begin{equation*}
S\left(q^{2}\right)=-\frac{6 \pi b}{q^{4}} \tag{14}
\end{equation*}
$$

The lattice calculation shows that the behavior of the gluon propagator is quite different in the nonperturbative region. The gluon may get a mass of about $600-1000 \mathrm{MeV}$ [19-21]. With the gluon getting a mass in the nonperturbative region, we can make the non-relativisitc approximation $q^{2} \rightarrow q^{2}-m_{\mathrm{g}}^{2} \approx-m_{\mathrm{g}}^{2}$ in the quark-antiquark pair-creation process. Thus

$$
\begin{align*}
D_{\mu \nu}\left(q^{2}\right) & \approx \frac{4 \pi \alpha_{\mathrm{s}} g_{\mu \nu}}{m_{\mathrm{g}}^{2}}  \tag{15}\\
D\left(q^{2}\right) & \approx-\frac{6 \pi b}{m_{\mathrm{g}}^{4}} \tag{16}
\end{align*}
$$

Then the channel coupling interaction is simplified to the four-fermion interaction

$$
\begin{align*}
\hat{V}= & -\frac{1}{2} \frac{4 \pi \alpha_{\mathrm{s}}}{m_{\mathrm{g}}^{2}} \int \mathrm{~d}^{3} x \bar{\psi}(\boldsymbol{x}) \gamma_{\mu} \frac{1}{2} \lambda_{\mathrm{a}} \psi(\boldsymbol{x}) \bar{\psi}(\boldsymbol{x}) \gamma^{\mu} \frac{1}{2} \lambda_{\mathrm{a}} \psi(\boldsymbol{x}) \\
& +\frac{1}{2} \frac{6 \pi b}{m_{\mathrm{g}}^{4}} \int \mathrm{~d}^{3} x \bar{\psi}(\boldsymbol{x}) \frac{1}{2} \lambda_{\mathrm{a}} \psi(\boldsymbol{x}) \bar{\psi}(\boldsymbol{x}) \frac{1}{2} \lambda_{\mathrm{a}} \psi(\boldsymbol{x}) \tag{17}
\end{align*}
$$

Once we calculate the transition amplitudes

$$
\begin{equation*}
f_{i}(\boldsymbol{p})=\left\langle\psi_{\alpha}\right| \hat{V}\left|M_{1}(i) M_{2}(i)\right\rangle \tag{18}
\end{equation*}
$$

where $\boldsymbol{p}$ is the relative momentum between $M_{1}$ and $M_{2}$, the mass shifts are given by

$$
\begin{align*}
g(M) & =\sum_{i} g_{i}(M)  \tag{19}\\
g_{i}(M) & =\int \frac{f_{i}(\boldsymbol{p}) f_{i}(\boldsymbol{p})}{\left(m_{i 1}+m_{i 2}+\frac{p^{2}}{2 \mu_{i}}\right)-M} \mathrm{~d}^{3} p \tag{20}
\end{align*}
$$

where $m_{i 1}$ and $m_{i 2}$ are the masses of $M_{1}(i)$ and $M_{2}(i)$ mesons, $\mu_{i}$ is their reduced mass.

To calculate the coupling matrix element, we will use the simple harmonics oscillator ( $\mathrm{SHO} \mathrm{)} \mathrm{wave} \mathrm{func-}$ tions as usual. The partial-wave amplitude $f^{l s}$ can be expressed as

$$
\begin{equation*}
f^{l s}(\mathrm{~A} \rightarrow \mathrm{BC})=\pi^{-\frac{7}{4}} \beta_{\mathrm{A}}^{3 / 2} \mathrm{e}^{-\frac{m_{c}^{2}}{2\left(m_{\mathrm{q}}+m_{\mathrm{c}}\right)^{2}\left(\beta_{\mathrm{A}}^{2}+\beta_{\mathrm{B}}^{2}\right)^{2}} p^{2}} F^{l s}(p) \tag{21}
\end{equation*}
$$

where $\beta_{\mathrm{B}}=\beta_{\mathrm{C}}, m_{\mathrm{c}}$ is the mass of charm quark, $m_{\mathrm{q}}$ is the mass of light quarks $(\mathrm{u}, \mathrm{d}$, or s$) . F^{l s}(p)$ is a polynomial of $p$ which depends on the specific channel (the formulas are collected in Appendix A).

Our calculation is basically non-relativistic. However, the exponential factor in the obtained partialwave amplitude Eq. (21) is obviously not enough to cut off the high momentum contribution. We will make an additional cutoff to the momentum integration. The mass shift is then replaced by

$$
\begin{equation*}
g_{i}(M)=\int \frac{f_{i}(\boldsymbol{p}) f_{i}(\boldsymbol{p})}{\left(m_{i 1}+m_{i 2}+\frac{p^{2}}{2 \mu_{i}}\right)-M} \exp \left(-p^{2} / \Lambda^{2}\right) \mathrm{d}^{3} p \tag{22}
\end{equation*}
$$

where $\Lambda$ is the cutoff parameter.
Since the channel coupling calculation is essentially the virtual charmed meson loop calculation, the quark potential in the quark model should be renormalized [8]. The renormalization process can be outlined as follows. The full Hamiltonian is divided into

$$
\begin{equation*}
\hat{H}_{\mathrm{full}}=\hat{H}_{\mathrm{c}}+\Delta \hat{H} \tag{23}
\end{equation*}
$$

$\hat{H}_{\mathrm{c}}$ is the original quark model Hamiltonian. Its spectrum is given by

$$
\begin{equation*}
M_{\mathrm{nslj}}=M_{\mathrm{nl}}+\left\langle V_{\mathrm{HF}}\right\rangle\left\langle\boldsymbol{S}_{1} \cdot \boldsymbol{S}_{2}\right\rangle+\left\langle V_{\mathrm{LS}}\right\rangle\langle\boldsymbol{L} \cdot \boldsymbol{S}\rangle+\left\langle V_{\mathrm{T}}\right\rangle\langle T\rangle, \tag{24}
\end{equation*}
$$

where $M_{n l}$ is the centroid of $n l$ multiplet which is obtained from the spin-independent Hamiltonian $\hat{H}_{0}$ and the remaining terms give the fine splitting. $\langle T\rangle$ is the expectation value of the tensor operator,

$$
\langle T\rangle= \begin{cases}-\frac{1}{6} \frac{l+1}{2 l-1} & j=l-1  \tag{25}\\ \frac{1}{6} & j=l \\ -\frac{1}{6} \frac{l}{2 l+3} & j=l+1\end{cases}
$$

where the total spin $s=1 . \Delta \hat{H}$ is the cancellation term whose contribution should be added to the mass shift from coupled-channels to give the renormalized mass shift. The renormalized mass shift contains both a centroid correction and a fine splitting one. The centroid contribution will modify the quark central potential [8]. It is the fine splitting correction we will consider in this work.

## 3 Numerical calculation of fine splitting

In our calculation, the quark model is taken from Ref. [7]. The potential parameters are:
$\alpha_{\mathrm{s}}=0.55, \quad \sigma=0.175 \mathrm{GeV}^{2}, \quad m_{\mathrm{c}}=1.7 \mathrm{GeV}$,
$C=-0.271 \mathrm{GeV}, \quad m_{\mathrm{q}}=0.33 \mathrm{GeV}, \quad m_{\mathrm{s}}=0.5 \mathrm{GeV}$.

The SHO parameter $\beta$ is determined from the mean square radius of the meson state. The $\beta$ values of open-charm states are

$$
\begin{equation*}
\beta_{\mathrm{D}}=0.385 \mathrm{GeV}, \quad \beta_{\mathrm{D}_{\mathrm{S}}}=0.448 \mathrm{GeV} \tag{27}
\end{equation*}
$$

and the $\beta$ values of charmonium states are listed in Table 1.

Table 1. The $\beta$ values of charmonium states.

| $n L$ | $1 S$ | $2 S$ | $1 P$ | $2 P$ | $1 D$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\beta / \mathrm{GeV}$ | 0.676 | 0.485 | 0.514 | 0.435 | 0.461 |

In our calculation we take the gluon mass $m_{\mathrm{g}}=$ 640 MeV . This gives

$$
\begin{equation*}
\Gamma(\psi(3770) \rightarrow \mathrm{D} \overline{\mathrm{D}})=28.2 \mathrm{MeV} \tag{28}
\end{equation*}
$$

to fit the expermental value $27.3 \pm 1.0 \mathrm{MeV}$ [4].
To calculate the mass shift, we need to know the physical mass $M$ in Eq. (22). For the charmonium $1 S, 1 P$ and $2 S$ multiplets, we can directly use the experimental masses from PDG [4]. For the $2 P$ and $1 D$ multiplets, the physical masses are the predicted values calculated from the assignments of $\psi(3770)$ to $1^{3} D_{1}$ and $\mathrm{X}(3872)$ to $2^{3} P_{1}$.

The mass shifts are listed in Table 2. In our calculation we take the cutoff paramter $\Lambda=800 \mathrm{MeV}$. We also show the mass shifts without the integration cutoff. The cutoff reduces the mass shift by $\sim 15 \%$, which means that the contribution from high transfer momentum will be about $85 \%$ if we do not make the

cutoff in this non-relativistic calculation.
The fine splittings are listed in Table 3. For $1 S$, $1 P, 2 S$ states, the physical mass is the experimental mass. Then the fine splitting is calculated for each multiplet and listed as "splitting required". The fine splitting from the quark model is calculated from the bare masses of the quark model which are also taken from Ref. [7]. The fine splitting from coupledchannels are listed in the last column. So the total model fine splitting is the sum of the contributions from the quark model and from the coupledchannels. The results show that the calculated splittings fit the "splitting required" well in $1 S$ and $2 S$ multiplets. However in the $1 P$ multiplet, the model splittings seem too large.

Next, we turn to the $2 P$ and $1 D$ multiplets. This time, the "required spltting" is the sum of the splitting from the quark model and from the coupledchannels. For the $1 D$ multiplet, the $\psi(3770)$ is assig-

| $1^{1} D_{2}$ | 3793 | +0 | -0 | +1 |

ned to the $1^{3} D_{1}$ state. Then the masses of other states in the multiplet are calculated from the fine splittings as the prediction. The predicted mass of $1^{1} D_{2}$ is 3793 MeV . So the c $\overline{\mathrm{c}} 1^{1} D_{2}$ state is unlikely to be the experimental $\mathrm{X}(3872)$ state even when we have considered the fine splitting from coupled-channels. So we assign the $\mathrm{X}(3872)$ to the $2^{3} P_{1}$ state and calculate the masses of the rest states in the $2 P$ multiplet.

## 4 Summary

We have calculated the fine splitting in charmomium spectrum in the quark model with the channel coupling effect. The open charmed meson-meson channels below 4 GeV , including $\mathrm{DD}, \mathrm{DD}^{*}, \mathrm{D}^{*} \mathrm{D}^{*}$ and $D_{s} D_{s}, D_{s} D_{s}^{*}, D_{s}^{*} D_{s}^{*}$, are considered. The current-
current nonlocal interacting action is constructed from the color confinement and the one-gluon exchange interaction in the quark model. Using the massive gluon propagator from the lattice calculation in the nonperturbative region, the coupling interaction is further simplified approximately to the four-fermion interaction. The numerical calculation still prefers the assignment $1^{++}$of $\mathrm{X}(3872)$ after we consider the fine splitting effect from the coupledchannels. The $2 P$ and $1 D$ charmonium spectrum are estimated from the assignments of $1^{3} D_{1}$ to $\psi(3770)$ and $2^{3} P_{1}$ to $\mathrm{X}(3872)$.

We would like to thank professor Shi-Lin Zhu for the useful discussions.

## Appendix A

## The partial-wave amplitudes

The partial-wave amplitude is the sum of contribution from the confinement and from the coulomb interaction:

$$
\begin{equation*}
F^{l s}=\frac{6 \pi b}{m_{\mathrm{g}}^{4}} F_{\mathrm{conf}}^{l s}-\frac{4 \pi \alpha_{\mathrm{s}}}{m_{\mathrm{g}}^{2}} F_{\mathrm{coul} \cdot}^{l s} . \tag{A1}
\end{equation*}
$$

In the following,

$$
\begin{align*}
D_{k}^{i j} & =\frac{\beta_{\mathrm{A}}^{i} \beta_{\mathrm{B}}^{j}}{\left(\beta_{\mathrm{A}}^{2}+\beta_{\mathrm{B}}^{2}\right)^{k / 2}}  \tag{A2a}\\
\xi_{\mathrm{q}} & =\frac{m_{\mathrm{q}}}{m_{\mathrm{q}}+m_{\mathrm{c}}}  \tag{A2b}\\
\xi_{\mathrm{c}} & =\frac{m_{\mathrm{c}}}{m_{\mathrm{q}}+m_{\mathrm{c}}} \tag{A2c}
\end{align*}
$$

For the confinement, $F_{\text {conf }}^{l s}$ can be represented as

$$
\begin{equation*}
F_{\mathrm{conf}}^{l s}=\frac{1}{m_{\mathrm{q}}} F_{l}(p) C^{l s}, \tag{A3}
\end{equation*}
$$

where $C^{l s}$ is a spin-orbit recoupling coefficient

$$
C^{l s}=(-1)^{s_{\mathrm{C}}+s+l_{\mathrm{A}}+j_{\mathrm{A}}}\left\{\begin{array}{ccc}
s_{\mathrm{A}} & s & 1  \tag{A4}\\
l & l_{\mathrm{A}} & j_{\mathrm{A}}
\end{array}\right\}\left\{\begin{array}{ccc}
\frac{1}{2} & \frac{1}{2} & s_{\mathrm{B}} \\
\frac{1}{2} & \frac{1}{2} & s_{\mathrm{C}} \\
s_{\mathrm{A}} & 1 & s
\end{array}\right\} \sqrt{6(2 s+1)\left(2 l_{\mathrm{A}}+1\right)\left(2 s_{\mathrm{A}}+1\right)\left(2 s_{\mathrm{B}}+1\right)\left(2 s_{\mathrm{C}}+1\right)}
$$

The $F_{l}(p)$ is the polynomial of transfer momentum $p$ :

$$
\begin{align*}
& F_{p}(1 S \rightarrow 1 S+1 S)=-\frac{8}{3 \sqrt{3}}\left(\xi_{\mathrm{c}} D_{5}^{05}+2 \xi_{\mathrm{q}} D_{3}^{03}\right) p  \tag{A5}\\
& F_{p}(2 S \rightarrow 1 S+1 S)=\frac{4 \sqrt{2}}{9}\left\{\left[\xi_{\mathrm{c}}\left(7 D_{7}^{25}-3 D_{7}^{07}\right)+6 \xi_{\mathrm{q}}\left(D_{5}^{23}-D_{5}^{05}\right)\right] p-2 \xi_{\mathrm{c}}^{2}\left(\xi_{\mathrm{c}} D_{9}^{25}+2 \xi_{\mathrm{q}} D_{7}^{23}\right) p^{3}\right\}  \tag{A6}\\
& F_{s}(1 P \rightarrow 1 S+1 S)=-\frac{8 \sqrt{2}}{9 \sqrt{3}}\left[3 D_{5}^{15}-\xi_{\mathrm{c}}\left(\xi_{\mathrm{c}} D_{7}^{15}+2 \xi_{\mathrm{q}} D_{5}^{13}\right) p^{2}\right] \tag{A7}
\end{align*}
$$

$$
\begin{align*}
& F_{d}(1 P \rightarrow 1 S+1 S)=-\frac{16}{9 \sqrt{3}} \xi_{\mathrm{c}}\left(\xi_{\mathrm{c}} D_{7}^{15}+2 \xi_{\mathrm{q}} D_{5}^{13}\right) p^{2}  \tag{A8}\\
& F_{s}(2 P \rightarrow 1 S+1 S)=\frac{8}{9 \sqrt{15}}\left\{15\left(D_{7}^{35}-D_{7}^{17}\right)-5 \xi_{\mathrm{c}}\left[\xi_{\mathrm{c}}\left(3 D_{9}^{35}-D_{9}^{17}\right)+2 \xi_{\mathrm{q}}\left(D_{7}^{33}-D_{7}^{15}\right)\right] p^{2}+2 \xi_{\mathrm{c}}^{3}\left(\xi_{\mathrm{c}} D_{11}^{35}+2 \xi_{\mathrm{q}} D_{9}^{33}\right) p^{4}\right\}  \tag{A9}\\
& F_{d}(2 P \rightarrow 1 S+1 S)=\frac{8 \sqrt{2}}{9 \sqrt{15}}\left\{\xi_{\mathrm{c}}\left[\xi_{\mathrm{c}}\left(9 D_{9}^{35}-5 D_{9}^{17}\right)+10 \xi_{\mathrm{q}}\left(D_{7}^{33}-D_{7}^{15}\right)\right] p^{2}-2 \xi_{\mathrm{c}}^{3}\left(\xi_{\mathrm{c}} D_{11}^{35}+2 \xi_{\mathrm{q}} D_{9}^{33}\right) p^{4}\right\}  \tag{A10}\\
& F_{p}(1 D \rightarrow 1 S+1 S)=-\frac{16 \sqrt{2}}{45}\left[5 \xi_{\mathrm{c}} D_{7}^{25} p-\xi_{\mathrm{c}}^{2}\left(\xi_{\mathrm{c}} D_{9}^{25}+2 \xi_{\mathrm{q}} D_{7}^{23}\right) p^{3}\right]  \tag{A11}\\
& F_{f}(1 D \rightarrow 1 S+1 S)=-\frac{16}{15 \sqrt{3}} \xi_{\mathrm{c}}^{2}\left(\xi_{\mathrm{c}} D_{9}^{25}+2 \xi_{\mathrm{q}} D_{7}^{23}\right) p^{3} \tag{A12}
\end{align*}
$$

For the one-gluon exchange, $F_{\text {coul }}^{l s}$ is further decomposed to

$$
\begin{equation*}
F_{\mathrm{coul}}^{l s}=\frac{1}{m_{\mathrm{q}}} F_{1 l}(p) C^{l s}+\frac{1}{m_{\mathrm{c}}} F_{2 l}(p) C^{l s}-\frac{1}{m_{\mathrm{c}}} F_{1 l}(p) C_{2}^{l s}, \tag{A13}
\end{equation*}
$$

where $C_{2}^{l s}$ is another spin-orbit recoupling coefficient.

1) $s_{\mathrm{A}}=s_{\mathrm{B}}=s_{\mathrm{C}}=1$

$$
C_{2}^{l s}=(-1)^{l_{\mathrm{A}}+j_{\mathrm{A}}} \sqrt{2(2 s+1)\left(2 l_{\mathrm{A}}+1\right)}\left\{\begin{array}{ccc}
l_{\mathrm{A}} & 1 & l \\
s & j_{\mathrm{A}} & 1
\end{array}\right\}
$$

2) $s_{\mathrm{A}}=1, s_{\mathrm{B}}=s_{\mathrm{C}}=0$

$$
C_{2}^{l=j_{\mathrm{A}}, s=0}=-\sqrt{\frac{2\left(2 l_{\mathrm{A}}+1\right)}{2 j_{\mathrm{A}}+1}}
$$

3) $s_{\mathrm{A}}=s_{\mathrm{B}}=1, s_{\mathrm{C}}=0$

$$
C_{2}^{l, s=1}=(-1)^{l_{\mathrm{A}}+j_{\mathrm{A}}+1} \frac{\sqrt{3\left(2 l_{\mathrm{A}}+1\right)}}{2}\left\{\begin{array}{lll}
1 & 1 & 1 \\
l & l_{\mathrm{A}} & j_{\mathrm{A}}
\end{array}\right\}
$$

4) $s_{\mathrm{A}}=0$

$$
C_{2}^{l, s=1}=0
$$

The polynomials $F_{1 l}(p)$ and $F_{2 l}(p)$ are:

$$
\begin{align*}
& F_{1 p}(1 S \rightarrow 1 S+1 S)=\frac{8}{3 \sqrt{3}} \xi_{\mathrm{c}}\left(D_{3}^{03}-D_{5}^{23}\right) p  \tag{A14}\\
& F_{2 p}(1 S \rightarrow 1 S+1 S)=\frac{8}{3 \sqrt{3}} \xi_{\mathrm{c}}\left(D_{3}^{03}+D_{5}^{23}\right) p  \tag{A15}\\
& F_{1 p}(2 S \rightarrow 1 S+1 S)=-\frac{4 \sqrt{2}}{9}\left[\xi_{\mathrm{c}}\left(7 D_{7}^{25}-3 D_{7}^{43}+3 D_{5}^{23}-3 D_{5}^{05}\right) p+2 \xi_{\mathrm{c}}^{3}\left(D_{9}^{43}-D_{7}^{23}\right) p^{3}\right]  \tag{A16}\\
& F_{2 p}(2 S \rightarrow 1 S+1 S)=\frac{4 \sqrt{2}}{9}\left[\xi_{\mathrm{c}}\left(7 D_{7}^{25}-3 D_{7}^{43}-3 D_{5}^{23}+3 D_{5}^{05}\right) p+2 \xi_{\mathrm{c}}^{3}\left(D_{9}^{43}+D_{7}^{23}\right) p^{3}\right]  \tag{A17}\\
& F_{1 s}(1 P \rightarrow 1 S+1 S)=\frac{8 \sqrt{2}}{9 \sqrt{3}}\left[3 D_{5}^{15}+\xi_{\mathrm{c}}^{2}\left(D_{7}^{33}-D_{5}^{13}\right) p^{2}\right]  \tag{A18}\\
& F_{2 s}(1 P \rightarrow 1 S+1 S)=-\frac{8 \sqrt{2}}{9 \sqrt{3}}\left[3 D_{5}^{15}+\xi_{\mathrm{c}}^{2}\left(D_{7}^{33}+D_{5}^{13}\right) p^{2}\right]  \tag{A19}\\
& F_{1 d}(1 P \rightarrow 1 S+1 S)=-\frac{16}{9 \sqrt{3}} \xi_{\mathrm{c}}^{2}\left(D_{7}^{33}-D_{5}^{13}\right) p^{2}  \tag{A20}\\
& F_{2 d}(1 P \rightarrow 1 S+1 S)=\frac{16}{9 \sqrt{3}} \xi_{\mathrm{c}}^{2}\left(D_{7}^{33}+D_{5}^{13}\right) p^{2} \tag{A21}
\end{align*}
$$

$$
\begin{align*}
& F_{1 s}(2 P \rightarrow 1 S+1 S)=-\frac{8}{9 \sqrt{15}}\left[15\left(D_{7}^{35}-D_{7}^{17}\right)-5 \xi_{\mathrm{c}}^{2}\left(3 D_{9}^{35}+D_{9}^{53}-D_{7}^{33}-D_{7}^{15}\right) p^{2}-2 \xi_{\mathrm{c}}^{4}\left(D_{11}^{53}-D_{9}^{33}\right) p^{4}\right]  \tag{A22}\\
& F_{2 s}(2 P \rightarrow 1 S+1 S)=\frac{8}{9 \sqrt{15}}\left[15\left(D_{7}^{35}-D_{7}^{17}\right)-5 \xi_{\mathrm{c}}^{2}\left(3 D_{9}^{35}-D_{9}^{53}-D_{7}^{33}+D_{7}^{15}\right) p^{2}-2 \xi_{\mathrm{c}}^{4}\left(D_{11}^{53}+D_{9}^{33}\right) p^{4}\right]  \tag{A23}\\
& F_{1 d}(2 P \rightarrow 1 S+1 S)=-\frac{8 \sqrt{2}}{9 \sqrt{15}}\left[\xi_{\mathrm{c}}^{2}\left(9 D_{9}^{35}-5 D_{7}^{15}+5 D_{7}^{33}-5 D_{9}^{53}\right) p^{2}+2 \xi_{\mathrm{c}}^{4}\left(D_{11}^{53}-D_{9}^{33}\right) p^{4}\right]  \tag{A24}\\
& F_{2 d}(2 P \rightarrow 1 S+1 S)=\frac{8 \sqrt{2}}{9 \sqrt{15}}\left[\xi_{\mathrm{c}}^{2}\left(9 D_{9}^{35}+5 D_{7}^{15}-5 D_{7}^{33}-5 D_{9}^{53}\right) p^{2}+2 \xi_{\mathrm{c}}^{4}\left(D_{11}^{53}+D_{9}^{33}\right) p^{4}\right]  \tag{A25}\\
& F_{1 p}(1 D \rightarrow 1 S+1 S)=\frac{16 \sqrt{2}}{45}\left[5 \xi_{\mathrm{c}} D_{7}^{25} p+\xi_{\mathrm{c}}^{3}\left(D_{9}^{43}-D_{7}^{23}\right) p^{3}\right]  \tag{A26}\\
& F_{2 p}(1 D \rightarrow 1 S+1 S)=-\frac{16 \sqrt{2}}{45}\left[5 \xi_{\mathrm{c}} D_{7}^{25} p+\xi_{\mathrm{c}}^{3}\left(D_{9}^{43}+D_{7}^{23}\right) p^{3}\right]  \tag{A27}\\
& F_{1 f}(1 D \rightarrow 1 S+1 S)=-\frac{16}{15 \sqrt{3}} \xi_{\mathrm{c}}^{3}\left(D_{9}^{43}-D_{7}^{23}\right) p^{3}  \tag{A28}\\
& F_{2 f}(1 D \rightarrow 1 S+1 S)=\frac{16}{15 \sqrt{3}} \xi_{\mathrm{c}}^{3}\left(D_{9}^{43}+D_{7}^{23}\right) p^{3} . \tag{A29}
\end{align*}
$$
